Dataset: Maven Fuzzy Factory (Maven Analytics) — a fictional D2C e-commerce retailer selling stuffed animals. Data runs Mar 2012 – Mar 2015. The dip at the end of the revenue trend is a partial dataset, not an actual business decline.

The headline numbers

Three years of trading data — Mar 2012 to Mar 2015. Revenue grew ~48x from launch. The business is real and growing, but hiding some significant inefficiencies underneath.

Monthly Revenue Trend – Maven Fuzzy Factory (2012-2015)

Not all traffic is worth the same

Revenue per session split by channel and device. Desktop beats mobile across every channel — but one channel stands out as a serious problem.

⚠ **Socialbook mobile generates \$0.57/session** — vs \$6.01 for direct desktop. That's a 10× gap. Once ad spend is factored in, this channel is almost certainly running at a loss. The fix is simple: cut or pause, reallocate budget to what's working.

gsearch drives everything — a risk

Session volume by channel. gsearch dominates at 316K sessions — which also means any change to Google's algorithm or CPC pricing hits the business hard.

! ~67% of all sessions come from gsearch. Heavy concentration in one paid channel is a strategic risk. The business needs to diversify — bsearch and direct traffic have comparable revenue/session but far less volume investment.

\$692K lost before anyone adds to cart

The full conversion funnel from session to order. The biggest drop isn't at checkout — it's right at the start.

56% of all sessions never reach the product page. At just a 10% improvement in that one step, the model recovers **\$692,066 in annual revenue**. This is a UX or content problem, not a traffic problem — the users are there, they're just not clicking through.

gsearch carries most of the opportunity

Recoverable revenue by channel at a 10% product page fix. The opportunity is concentrated where the volume is — which makes the fix even more urgent.

- **Total recoverable across all channels: \$692,066.** gsearch alone accounts for ~\$450K of that. Fixing the product page is the single highest-ROI action in this entire dataset — ahead of any channel optimisation.

~90% of users never come back

Cohort retention curves showing what percentage of users from each month return in subsequent months. The cliff at Month 1 is universal across all cohorts.

- Every cohort drops to below 10% retention by Month 1. The shape is consistent — strong acquisition, almost no repeat behaviour. Every user acquired but not retained inflates the effective cost per order. Email re-engagement is the clearest lever here.

But it's improving — 4.5% → 9.2%

Month-1 return rate by acquisition cohort. Later cohorts are stickier than earlier ones — a positive signal that something is working, even if the absolute level is still low.

- **Month-1 retention doubled from 4.5% to 9.2%** between the 2012 and 2014 cohorts. The trend is encouraging. Building a formal retention programme on top of this organic improvement could compound the gains significantly.

One product to push. One to fix.

Refund rate and cross-sell rate across 4 SKUs. The contrast between Mini Bear and Birthday Sugar Panda couldn't be more clear.

★ **Mini Bear: 89.4% cross-sell rate, 1.3% refund rate.** The best product in the range by every measure. Should be surfaced as a checkout upsell on every Mr. Fuzzy order — zero cost, instant lift.

! **Birthday Sugar Panda: 6% refund rate.** Nearly 5× higher than Mini Bear. Points to a quality or description mismatch. Needs investigation before sending more traffic its way.
